SYNTHESIS OF PYRROLYL AND PYRAZOLYL SULFONAMIDES

A new class of pyrrolyl and pyrazolyl sulfonamides was prepared from styrene-ω-sulfoanilides by treatment with tosylmethyl isocyanide and diazomethane, respectively.

**Keywords:** diazomethane, pyrazolylsulfonamide, pyrrolylsulfonamide, styrene-ω-sulfoanilides, tosylmethyl isocyanide.

Scientific efforts have continuously been directed towards the design and synthesis of five-membered heterocycles because of their utility as pharmacological agents. Netropsin and Distamycin are pyrrole polyamides and are naturally occurring anticancer antibiotics [1]. Multistep synthetic routes for 3,4-disubstituted pyrroles have been reported either by coupling of imines and nitroalkanes or using Friedel–Craft's acylation with an electron withdrawing group on pyrrole nitrogen or 3,4-silylated precursors [2]. Pyrroles have also been prepared from Michael acceptors and tosylmethyl isocyanide (TosMIC) [3, 4]. Several pyrazole derivatives received increased attention due to their biological activities as potential HIV-1 inhibitors [5], insecticides [6], fungicides [6], antiviral [7], anti-inflammatory [8], antiobesity [9] and anticancer agents [10]. Amongst different known methods for the synthesis of pyrazoles, Huisgen's 1,3-dipolar cycloaddition is a versatile one [11]. Recent syntheses of pyrazoles via 1,3-dipolar cycloaddition includes reaction of nitrile imines and alkynes [12] or enaminines [13], hydrazones and nitroolefins [14], diazocompounds and alkynes [15], and azomethine imines and alkynes [16]. We have exploited various activated olefins for the synthesis of a variety of mono- and bis-heterocycles [17, 18]. However, there are no reports to our knowledge about the use of styrenesulfonamides for the development of five-membered heterocycles.

The present communication deals with the synthesis of pyrrolyl and pyrazolyl sulfonamides from styrene-ω-sulfoanilides 1a–c. The compounds 1a–c were prepared by the Knoevenagel's condensation of arylaminosulfonylacetic acids with arylaldehydes. The arylaminosulfonylacetic acids were obtained by the well-known chain of reactions from substituted anilines [19].

The olefin group present in compounds 1a–c was exploited to develop pyrrole and pyrazoline rings. Treatment of compounds 1a–c with TosMIC gave 4-aryl-3-arylaminosulfonylpyrroles 2a–c. The 1H NMR spectrum of compound 2a showed two singlets at 6.56 and 7.17 ppm due to H-2 and H-5 protons of pyrrole ring in addition to two broad singlets at 8.41 and 10.45 ppm due to SO2NH and NH fragments. The latter signals disappeared by deuteration. Similarly 1,3-dipolar cycloaddition of diazomethane to compounds 1a–c at a temperature of about −20°C produced 4-aryl-3-arylaminosulfonyl-1-methylpyrazolines 3a–c. It appears that N-methylation also took place during the course of cyclization.
The $^1$H NMR spectrum of compound $3a$ showed AMX splitting pattern for methine and methylene protons of pyrazoline ring. The three double doublets observed at 4.22, 3.94 and 3.55 ppm were assigned to pyrazoline ring protons HA, HM andHX, respectively. The coupling constants indicated that HA and HM are in cis, HA andHX – trans, and HM andHX – in geminal position to each other. A sharp singlet was observed at 3.14 ppm due to NCH$_3$ group. Apart from these, a broad singlet was observed at 8.37 ppm due NH which disappeared on deuteration.

Aromatization of compounds $3a$–c with chloranil in xylene resulted in 4-aryl-3-arylaminosulfonyl-1-methylpyrazoles $4a$–c. The absence of AMX splitting pattern confirmed the formation of compounds $4a$–c. The $^1$H NMR spectrum of compound $4a$ displayed two sharp singlets due to NCH$_3$ group and H-5 proton (overlapping with multiplet signal of phenyl protons), and a broad singlet due to NH proton. The signal due to NH disappeared by deuteration. The structures of the compounds were further established by IR and $^{13}$C NMR spectra.

Thus, a simple substrate, styrene-$\omega$-sulfonanilide, was exploited to obtain a new sulfonamide linked pyrroles and pyrazoles adopting 1,3-dipolar cycloaddition methodology.

**EXPERIMENTAL**

The IR spectra were recorded on a Thermo Nicolet IR 200 FT-IR spectrometer in KBr pellets. The $^1$H and $^{13}$C NMR spectra were recorded on a Bruker Spectrospin instrument (400 and 100 MHz, respectively) in DMSO-$d_6$ using TMS as internal standard. The elemental microanalyses were performed on a Perkin Elmer 240C Elemental Analyzer. Melting points were determined in open capillaries on a Mel-Temp apparatus and are uncorrected. The purity of the compounds was checked by TLC (silica gel H, BDH, eluent EtOAc–hexane, 1:3). The starting arylaminsulfonylacetic acids were prepared by the literature procedure [19].

**Styrene-$\omega$-sulfonanilides 1a–c** (General Method). A mixture of arylaldehyde (1 mmol), pyridine (4 ml), AcONH$_4$ (1.00 g, 13 mmol), arylaminsulfonylacetic acid (0.21 g, 1 mmol), and toluene (25 ml) were refluxed for 20–24 h with azeotropic removal of water. The solution was
cooled and washed successively with dilute HCl, dilute Na₂SO₃, and brine. Then it was extracted with 10% KOH. The potassium salt of styrene sulfonamide was separated as oil with the aqueous phase. The two phase aqueous extract was washed with ether and acidified with HCl. Then, it was extracted with ether. Removal of the solvent under vacuum furnished a solid which on recrystallization from cyclohexane gave compounds 1a–c.
